5 Technical Field

The present invention relates to novel compounds and compositions which have antiviral activity, processes for making such compounds, synthetic intermediates employed in these processes and a method for treating a human or other mammal in need of antiviral treatment.

10

Background Art

15

Viruses are implicated in a variety of animal and human diseases. Numerous approaches have been proposed to combat these pathogens which include, but are not limited to, herpesviruses 1 and 2 (HSV-1 and HSV-2), influenza viruses A, B and C (orthomyxoviruses), parainfluenza viruses 1-4, mumps virus (paramyxovirus), adenoviruses, respiratory syncytial virus, Epstein-Barr virus, rhinoviruses, human immunodeficiency viruses (HIV), polioviruses, coxsackieviruses, echoviruses, rubella virus, varicella-zoster virus, neurodermatropic virus, variola virus, cytomegalovirus, hepatitis A, B and non-A, non-B viruses, papoviruses and rabies virus.

20

One approach in the development of antiviral compounds has been to identify compounds which interfere with the normal viral metabolism of nucleosides. Because the structures of these compounds are usually closely related to nucleosides which occur naturally in the mammalian host, few have good activity against the virus without untoward side effects. Some of the few compounds having activity are very expensive to produce. Thus, there is a continuing need for new compounds which act to kill viruses, to inhibit viral replication or to block the pathogenic actions of viruses.

 The compounds of the present invention can be prepared by various methods, including those disclosed in Schemes 1-4.
 A shown in Scheme 1, treatment of 1, wherein B is as defined herein, with a suitable alkyl halide,
 30 arylalkyl halide (e.g., triphenylmethyl chloride), aroyl halide, alkanoyl halide, or silyl halide (e.g., trimethylsilyl chloride) in a polar solvent such as N,N-dimethylformamide (DMF), tetrahydrofuran (THF), CH₂Cl₂ or pyridine at a temperature of from about 0° to about 60°C affords the protected derivative 2 (R' is an O-protecting group). Preferably, 1 is treated with t-butylchlorodimethylsilane in pyridine at room temperature for about 24 hours to obtain 2 (R' = (t-Bu)(Me)₂Si-).
 35 When the substituent B in 1 or 2 is a purine having a 6-amino substituent, the 6-amino substituent can be protected by acylation with an alkanoyl chloride (e.g., acetyl chloride and the like) or aroyl chloride (e.g., benzoyl chloride or p-nitrobenzoyl chloride or the like) or a corresponding anhydride such as acetic anhydride in a solvent such as pyridine. Subsequent treatment with a dilute aqueous base such as sodium carbonate, potassium carbonate, potassium hydroxide or preferably 1 M aqueous sodium hydroxide at a
 40 temperature of from about -20° to about 40°C, preferably at about 0°C, affords diprotected 2. In the preferred case, the benzoyl group is used to protect the 6-amino group. The two protecting groups can also be introduced in the reverse order of that described above.

The free hydroxyl group in 2 is converted to an activated ester leaving group by treatment with a sulfonyl chloride (e.g., p-toluenesulfonyl chloride or trifluoromethanesulfonyl chloride and the like) or sulfonic acid anhydride (e.g., methanesulfonic acid anhydride) in a solvent such as pyridine or dichloromethane, optionally containing a base such as triethylamine, at a temperature of from about -10° to about 40°C for a period of from about 1 hour to about 24 hours. In a preferred method, 2 is treated with methanesulfonyl chloride in pyridine at 0°C for 2 hours to provide 3 (R'' = -SO₂Me). The leaving group in 3 is then displaced with an appropriate nucleophile (Nu⁻) in a polar solvent such as acetone, 2-butanone, THF, DMF
 50 or dimethoxyethane (DME) to furnish 4. Suitable nucleophilic reagents include LiN₃, NaN₃, n-Bu₄NN₃, KF, CsF, n-Bu₄NF, LiBr, NaBr, n-Bu₄NBr, LiI, NaI, n-Bu₄NI, LiCl, n-Bu₄NCl, CH₃CH₂NH₂, CH₃NH₂ and lithium triethylborohydride. The compounds 4 thus obtained are converted to the compounds of this invention (I) by removal of the hydroxyl protecting group. In the preferred case in which B is 6-benzimidopurin-9-yl and R' is (t-Bu)(Me)₂Si-, the deprotection is accomplished with a source of fluoride ion such as KF, CsF or preferably n-Bu₄NNF in a polar solvent such as DMF, CH₃CN or preferably THF at a temperature of about 25°C. In the case in which a nitrogen protecting group has been employed, this group must also be removed. In the preferred case in which the nitrogen protecting group is benzoyl, treatment of 4 with dilute aqueous sodium hydroxide in methanol or sodium ethoxide in ethanol provides I.

An alternative preparation of 4 ($\text{Nu} = \text{F}$) involves direct treatment of the alcohol 2 with a fluorinating agent such as diethylaminosulfur trifluoride (DAST) in a nonhydroxylic solvent such as dichloromethane at a temperature between -78° and 25° C, preferably about -40° C. The amino derivative 4 ($\text{Nu} = -\text{NH}_2$) is obtained by reduction of the corresponding azide (4, $\text{Nu} = -\text{N}_3$).

- 5 preferably employing hydrogen and a palladium catalyst. These analogs 4 are converted to compounds of this invention as described above.

Compounds of formula I wherein B is a 6-alkylaminopurin-9-yl group or a 6-amidopurin-9-yl group can be synthesized according to the route outlined in Scheme 2. For example, treatment of 1a with sodium nitrite in acetic acid or an acetate buffer at a temperature of about -10° to 60° C affords the deaminated 10 material 6. Suitable conditions include the use of amyl nitrite in 50% acetic acid. Alternatively, this transformation can be accomplished enzymatically. The hydroxymethyl substituents on the oxetane ring of 15 5 are protected using an acylating agent such as nitrobenzoyl chloride or benzoylchloride in a solvent such as pyridine or DMF at a temperature of about -10° to 60° C. In the preferred method, 5 is treated with trifluoroacetic anhydride in CH_2Cl_2 at 0° to 20° C to obtain the diacyl derivative 6. Treatment of 6 with 20 DMF/thionyl chloride in dichloromethane, preferably at reflux temperature followed by cleavage of the acyl protecting groups, preferably using methanol and neutral alumina provides 7. Exposure of 7 to an amine ($\text{R}_a\text{R}_b\text{NH}$, wherein R_a and R_b are independently selected from $\text{C}_1\text{-C}_{10}$ alkyl and hydrogen), at a temperature of from about 25° C to about 200° C furnishes 8. A preferred method involves the reaction of 7 with methylamine at about 100° C to afford 8. Compound 1 in Scheme 1 may be replaced with the compounds 8 of Scheme 2 to obtain the corresponding N-6 substituted derivatives I.

The compounds of the invention of the formula I can be prepared as shown in Scheme 3, where "P" is a hydroxyl protecting group intended to protect against undesirable side reactions during synthetic procedures. "P" includes, but is not limited to, t-butyldimethylsilyl, t-butyldiphenylsilyl, triphenylmethyl, benzoyl, acetyl and the like. "B" is as defined above.

- 25 The process shown in the scheme entails ring contraction of a 3-deoxy nucleoside 11 to an oxetane ring via rearrangement of the diazoketone 12.

Scheme 4 shows the process outlined in Scheme 3 wherein B is thymine, cytosine or uracil. P' and P" are hydroxyl protecting groups intended to protect against undesirable side reactions during synthetic procedures. P' and P" are independently selected from hydroxyl protecting groups including, but not limited 30 to, t-butyldimethylsilyl, triphenylmethyl, benzoyl, p-chlorobenzoyl, acetyl, benzyl and the like.

The process shown in Scheme 4 entails ring contraction of a 2',3'-dideoxy-2'-oxo nucleoside 11 - (wherein the hydroxyl protecting group P' is preferably t-butyldimethylsilyl) to an oxetane ring via rearrangement of the diazoketone 12, followed by reduction of the ester 13 (R'' is loweralkyl, for example, CH_3) to the 2'-hydroxymethyl compound 14 and removal of the hydroxyl protecting group to give I.

In the case where B is uracil, the epoxide 15 (wherein the 5'-hydroxyl protecting group P' is preferably 35 a benzoyl group) is opened to compound 16 by treatment with an iodide salt such as sodium iodide in the presence of an acid in a polar solvent such as 2-butanone. The iodo derivative 16 is reduced to 10 preferably with tri-n-butyl tin hydride and the 5'-hydroxyl group deprotected, for example by treatment with t-potassium carbonate in methanol solution. The 5'-hydroxyl group is reprotected, preferably with a t-40 butyldimethylsilyl group and the 2'-hydroxyl group is oxidized to the ketone to afford compound 11, for example by treatment with chromium trioxide-pyridine reagent.

In the case where B is thymine, 3'deoxy-5-methyluridine with both sugar hydroxyls protected (compound 17, P' and P" are O-protecting groups), preferably as p-chlorobenzoyl esters, is deprotected in basic solution, for example using sodium methoxide in methanol solution. The 5'-hydroxyl group is 45 selectively reprotected (P'), preferably as the t-butyldimethylsilyl (TBS) derivative and the 2'-hydroxyl group is oxidized by treatment with oxidizing agent such as chromium trioxide-pyridine reagent to afford 11.

In the case where B is cytosine, cytosine with the 4-amino group protected as the N-acetyl derivative is treated with hexamethyldisilazane to give 18. Compound 18 is coupled in the presence of tin tetrachloride with 1-O-acetyl-3-deoxyribose, preferably with the 2'- and 5'-hydroxyl groups protected (P' and P" are O-50 protecting groups) as p-chlorobenzoyl esters (20) to give compound 19. The protecting groups are then removed from the 2'- and 5'-hydroxyl groups, for example by treatment with ammonium hydroxide in methanol solution, and the 5'-hydroxyl group selectively reprotected, preferably by treatment with t-butyldimethylsilyl chloride. The 4-amino group is reprotected, preferably as the N,N-dimethylaminomethylene derivative, and the 2'-hydroxyl group is then oxidized, for example with DMSO in the presence of oxalyl chloride, to afford 11.

Scheme 5a shows the conversion of protected diol 14 to the monohydroxy compound 21. Oxidation (for example, with Dess-Martin periodinane) of 14 to aldehyde 19, followed by deformylation (for example, with tris(triphenylphosphine)ruthenium (I)), provides 20. Deprotection then gives 21.

Scheme 5b shows the preparation of triol 24 and diol 25. Compound 22 wherein L is a leaving group (for example, mesylate) is treated with a base (for example, DBU) to provide olefin 23. Oxidation (for example with N-methylmorpholine-N-oxide/OsO₄), followed by deprotection, provides triol 24. Oxidation of 24 (for example, with sodium periodate), followed by reduction (for example, with sodium borohydride), gives the diol 25.

As used in the following examples, the references to compounds, such as (1), (2), (3), etc., and to substituents, such as R, R_a, R_b, etc., refer to the corresponding compounds and substituents in the foregoing reaction schemes and formulae.

The following examples will serve to further illustrate preparation of the novel compounds of the invention.

50 Example 1

9-((2R,3R,4S)-4-Hydroxymethyl-3-methyl-oxetan-2-yl) adenine

(a) In a round-bottom flask were placed 10 g of 9-((2R,3R,4S)-3,4-bis-hydroxymethyl-oxetan-2-yl)-adenine and 100 mL of pyridine. To the system was added 6.4 g of tert-butylchlorodimethylsilane, and the reaction mixture was stirred under nitrogen at room temperature for 1 day. The mixture was diluted with ethyl acetate and washed with saturated aqueous sodium bicarbonate and brine, dried (sodium sulfate) and concentrated with a rotary evaporator. The residue was purified by column chromatography to afford 9-((2R, 3R, 4S)-4-t-butyldimethylsiloxyethyl-3-hydroxymethyl-oxetan-2-yl)adenine.

- (b) Under a nitrogen atmosphere, in a round-bottom flask were placed 1.8 g of the product of (a) and 8 mL of dichloromethane. To this stirring solution, at 0 °C, were added 1.1 g of triethylamine and 0.69 g of methanesulfonyl chloride. The cold bath was removed, and the reaction mixture was stirred at room temperature for approximately 2 h. The reaction mixture was diluted with ethyl acetate, washed with saturated aqueous sodium bicarbonate and brine and dried over sodium sulfate. The solvent was removed with a rotary evaporator to afford 9-(2R, 3R, 4S)-4-t-butylidimethylsiloxyethyl-3-methanesulfonyloxyethyl-oxetan-2-yl) adenine.
- (c) Under a nitrogen atmosphere, in a roundbottom flask were placed 0.44 g of the compound of (b) and 0.5 mL of THF. To this stirring solution, at 0 °C, was added 1.2 mL of 1 M lithium triethylborohydride in THF. The cold bath was removed, and the reaction mixture was stirred at room temperature for 4 h. The mixture was partitioned between ethyl acetate and saturated aqueous sodium bicarbonate. The layers were separated, and the organic phase was washed with brine, dried (Na_2SO_4) and concentrated with a rotary evaporator. The residue was purified by column chromatography to afford 9-((2R, 3R, 4S)-4-t-butylidimethylsiloxyethyl-3-methyl-oxetan-2-yl)adenine.
- (d) Under a nitrogen atmosphere, in a round-bottom flask was placed 0.35 g of the compound of (c). To the system was added 1.4 mL of 1 M n-Bu₄NF in THF. The reaction mixture was stirred at room temperature for 6 h and concentrated with a rotary evaporator. The residue was triturated with aqueous methanol and the resulting solid I ($X = \text{CH}_3$, $R_a = R_b = \text{H}$) was collected by suction filtration, rinsed with ice cold methanol and ether and dried under vacuum.

Example 2

9-((2R, 3R,4S)-3-Fluoromethyl-4-hydroxymethyl-oxetan-2-yl)adenine

The procedures of Examples 1(a) and 1(b) can be repeated to obtain 9-((2R, 3R, 4S)-4-t-butylidimethylsiloxyethyl-3-methanesulfonyloxyethyl-oxetan-2-yl) adenine.

Under a nitrogen atmosphere, in a round-bottom flask was placed 0.44 g of the foregoing compound. To the system was added 8 mL of 1 M n-Bu₄NF, and the reaction mixture was heated at reflux for 4 h. The mixture was cooled to room temperature and concentrated with a rotary evaporator. Trituration of the resulting viscous oil with MeOH-H₂O afforded a white solid which was collected by suction filtration, rinsed with ice-cold methanol and ether and dried under vacuum.

Step 1: 5-Methyl-3'-deoxyuridine

2',5'-bis(O-(4"-Chloro)benzoyl)-5-methyl-3'-deoxyuridine (M. Saneyoshi, et al. Chem Pharm Bull. 30,

2223-7 (1982)) was deprotected in methanolic sodium methoxide. The 2',5'-bis(O-(4"-chloro)benzoyl)-5-methyl-3'-deoxyuridine (12.53 g, 24.19 mmol) was dissolved in 1 L of methanol (MeOH) containing 2.613 g (48.38 mmol) of sodium methoxide. The reaction mixture was stirred at ambient temperature for approximately 1.5 h. At this time TLC analysis on silica gel plates eluted with 10% MeOH in methylene chloride indicated that the reaction had gone to completion. The solution was concentrated under reduced pressure and diluted with water. The aqueous solution was neutralized with Amberlite IR-120® acidic resin and the resultant suspension filtered. The filtrate was concentrated under reduced pressure and the residue taken up in dry pyridine. The pyridine was removed in vacuo and the residue redissolved in dry pyridine and reconcentrated in vacuo. The residue was dried in vacuo for approximately 64 h at ambient temperature to yield 8.6 g of the title compound, which was taken on to the next step without purification.

Step 2: 5'-O-(t-Butyldimethylsilyl)-5-methyl-3'-deoxyuridine

5-Methyl-3'-deoxyuridine, from Step 1, was dissolved in 150 mL of dry pyridine and 3.6 g (24 mmol) of t-butyldimethylsilyl chloride was added in 4 portions at 4 times (t): t=0 h, t=2 h, t=3 h and at t=3.75 h. After 4.5 h, 8 mL of methanol was added to the reaction mixture and the reaction mixture was stirred for 0.5 h, then concentrated under reduced pressure to approximately 25% of volume. The concentrated reaction mixture was diluted with ethyl acetate, washed with dilute aqueous sodium bicarbonate solution and then concentrated under reduced pressure. The residue was purified by column chromatography on a 5 cm x 37 cm silica gel column eluted with 90% ethyl acetate in hexane. The fractions containing the desired product were combined and concentrated in vacuo to give 7.27 g (84.4% yield, based on 24.19 mmol of 2',5'-bis(O-(4"-chloro)benzoyl)-5-methyl-3'-deoxyuridine) of 5'-O-(t-butyldimethylsilyl)-5-methyl-3'-deoxyuridine, $[\alpha]_D^{23} = -19.6^\circ$ (c, 1.42, MeOH). Analysis calculated for $C_{16}H_{28}N_2O_5Si$: C, 53.98; H, 7.91; N, 7.87. Found: C, 54.01; H, 7.85; N, 7.79.

Chromium trioxide (7.63 g, 76.3 mmol) was added to 150 mL of dry methylene chloride containing 12.059 g (152.6 mmol) of pyridine. The mixture was stirred for 15 minutes. In a separate flask, 793 mg (19.08 mmol) of 5'-O-(t-butyldimethylsilyl)-5-methyl-3'-deoxyuridine from Step 2 was dissolved in approximately 100 mL of methylene chloride. The chromium trioxide-pyridine solution was added to the solution of 5'-O-(t-butyldimethylsilyl)-5-methyl-3'-deoxy-uridine and 1.946 g (19.08 mmol) of acetic anhydride was added immediately. After stirring at ambient temperature for 0.5 h, the reaction mixture was diluted with approximately 250 mL of ethyl acetate then filtered through Celite filter aid and through florisil eluted with ethyl acetate. The solvent was evaporated and the residue purified on silica gel eluted with 90% ethyl acetate in hexanes. The title compound was obtained in 59.6% yield (4.08 g), $[\alpha]_D^{23} = +38.0^\circ$ (c, 1.31, MeOH). Analysis calculated for $C_{16}H_{26}N_2O_5Si$: C, 54.24; H, 7.34; N, 7.91. Found: C, 54.25; H, 7.36; N, 7.88

The trifluoromethanesulfonyl azide solution was prepared as follows: Sodium azide (19.8 g, 0.305 mol) was dissolved in 50 mL of water and 62 mL of 1,2-dichloroethane was added. The mixture was cooled in an ice bath and 17.2 g (61 mmol) of trifluoromethanesulfonyl anhydride was added dropwise. After the addition was complete, the mixture was stirred at 0 °C for 2 h. 1,2-Dichloroethane (10 mL) was added, the layers separated and the aqueous layer extracted with 2 X 5 mL of 1,2-dichloroethane. The combined organic layer was washed with 1 N sodium hydroxide

solution and brine, dried over anhydrous magnesium sulfate and filtered.

The reaction mixture was heated in an oil bath at 60 °C for 2 h and concentrated (to approximately 30 mL) under reduced pressure. The solution was chromatographed on a silica gel column (3.0 X 30 cm) eluted with 50% ethyl acetate in hexanes. 35 Example 22

1-([2'R,3'R,4'S]-3',4'-Bis(hydroxymethyl)-2'-oxetanyl)cytosine

Step 1: 4-(N-Acetyl)-2',5'-bis(O-(4"-chloro)benzoyl)-3'-deoxycytidine

40 4-N-Acetyl cytosine (1.935 g, 12.6 mmol), prepared as described by P. Angibeaud, et al. in *Carbohydrate Research*, 78, 195-204 (1980), was dissolved in 100 mL of hexamethyldisilazane containing 50 mg of ammonium sulfate and the solution was heated at reflux temperature for 3 h. Solvent was then removed by

azeotropic distillation with toluene. The residue was dried *in vacuo* for 1 h and then dissolved in 30 mL of acetonitrile. 1-O-Acetyl-2,5-bis(O-(4'-chloro)benzoyl)-3'-deoxyribose (5.145 g, 11.4 mmol) dissolved in 30 mL of acetonitrile was added, followed by 3.85 g (1.73 mL, 14.8 mmol) of tin tetrachloride. The solution was stirred at ambient temperature overnight and the solvents evaporated under reduced pressure. Saturated aqueous sodium bicarbonate solution was added to neutralize the residue and ethanol was added before removing the water under vacuum. The solid residue was extracted three times with hot acetone. The combined filtrate (the acetone solution) was concentrated under reduced pressure and the residue triturated with isopropyl alcohol to give 3.70 g of the desired product. A small amount (0.438 g) of the desired product also crystallized from the isopropyl alcohol "mother liquor". The solid which had been extracted with hot acetone was found to contain additional product which was extracted with two portions of methylene chloride. The total yield of 4-(N-acetyl)-2',5'-bis(O-(4"-chloro)benzoyl)-3'-deoxycytidine was 5.01 g (84.5% yield).

The 1-O-acetyl-2,5-bis(O-(4'-chloro)benzoyl)-3'-deoxyribose used in the above synthesis was prepared as follows: Adenosine was converted to 2',3'-cideoxy-2',3'-epoxyadenosine by the method described by F. Hansske and J. Robins in *Tetrahedron Letters*, 4295-8 (1985) using 100:1 acetonitrile:water as solvent, not 10:1 as reported. The epoxide was reduced to 3'-deoxyadenine as described in the same reference, using 2.1 equivalents of lithium triethylborohydride in THF, instead of the 12.5 equivalents of lithium triethylborohydride in DMSO reported. Benzoyl protecting groups were introduced as described by M. Sanyoshi, et al. in *Chem Pharm Bull*, 30, 2223-7 (1982) and the sugar was cleaved from the purine base as described in the same reference, with the exception that 1 equivalent, not 15 equivalents as reported) of concentrated sulfuric acid was used.

Step 2: 5'-O-(t-Butyldimethylsilyl)-3'-deoxycytidine

4-(N-Acetyl)-2',5'-bis(O-(4"-chloro)benzoyl)-3'-deoxycytidine (5.0 g, 9.6 mmol), from Step 1, was treated with 200 mL of methanol and 200 mL of concentrated ammonium hydroxide at 55 °C for 5.5 h. The solvent was evaporated under reduced pressure and the residue dried under vacuum overnight. The dry residue was dissolved in 40 mL of dry pyridine and 1.447 g (9.6 mmol) of t-butyldimethylsilyl chloride was added. After the reaction mixture was stirred at ambient temperature for 50 minutes a second 9.6 mmol portion of t-butyldimethylsilyl chloride was added, followed by 1.632 g (24 mmol) of imidazole. After stirring the reaction mixture for approximately 3 h, 5 mL of methanol was added and the solution stirred for approximately 0.5 h. The solution was concentrated under reduced pressure to approximately 1/3 of original volume and diluted with methylene chloride. The resultant solution was partitioned between saturated aqueous sodium bicarbonate and ethyl acetate and the layers separated. The organic layer was dried over anhydrous magnesium sulfate, filtered and concentrated *in vacuo*. The residue was purified on a silica gel column (3 X 30 cm) eluted with 10% methanol in methylene chloride. Fractions containing the incompletely purified product were combined, concentrated under reduced pressure and rechromatographed on a silica gel column (2 X 40 cm) eluted with 10% methanol in methylene chloride to give the desired product. The pure product from the first and second column were combined to give 1.38 g (42% yield) of 5'-O-(t-butyldimethylsilyl)-3'-deoxycytidine. MS DCI M/Z: 342 (M + H)⁺.

The solvent was removed *in vacuo* to give 5'-O-(t-butyldimethylsilyl)-3'-deoxy-4-(N-(N',N'-dimethyl)aminomethylene)-cytidine which was taken on without purification. Dimethylsulfoxide (209 μL, 2.70 mmol) was added to 8 mL of dry methylene chloride and the solution was cooled in a dry ice-acetone bath. Oxalyl chloride (193 μL, 2.21 mmol) was added, followed by (after 17 minutes) 5'-O-(t-butyldimethylsilyl)-3'-deoxy-4-(N-(N',N'-dimethyl)aminomethylene)-cytidine dissolved in 4 mL of methylene chloride. After stirring the reaction mixture for 35 minutes at -78 °C, 819 μL of triethylamine was added and after an additional 45 minutes, approximately 3 mL of 10% aqueous citric acid solution was added. The reaction mixture was then allowed to warm to ambient temperature and diluted with methylene chloride, washed with 10% citric acid solution, saturated aqueous sodium bicarbonate solution and brine, dried over anhydrous magnesium sulfate, filtered and concentrated under reduced pressure to give 0.61 g of the title compound, which was taken on to the next step without purification.

The mixture was stirred in an ice bath for 2 h, diluted with 4 mL of 1,2-dichloroethane and the layers separated. The aqueous layer was extracted with 2 x 4 mL of 1,2-dichloroethane. The combined organic extract was washed with 1 M aqueous sodium hydroxide solution and brine, dried over anhydrous magnesium sulfate. 5'-O-(t-Butyldimethylsilyl)-2',3'-dideoxy-4-(N-(N',N'-dimethylamino)methylene)-3'-(N',N'-dimethylamino)methylene)-2'-oxo-cytidine from Step 4 was added to 20 mL of the trifluoromethanesulfonyl azide solution and the reaction mixture was heated in a 60 °C oil bath for 2 h, filtered and partially concentrated under reduced pressure. To a stirred solution of 435 mg (1 mmol) of 1-([2'R, 3'R, 4'S]-4'-(t-butyldimethylsilyl)oxymethyl)-3'-methanesulfonyloxyethyl-2'-oxetanyl-5-methyluracil, the product of Part a of Example 24, in 5 mL of acetonitrile is added 152 mg (1 mmol) of DBU, and the resulting mixture is heated to reflux for 1 to 24 hours. The antiviral activity of the compounds of the invention can be determined by the following methods.

A. Evaluation of Compounds for Activity Against Herpes Simplex Virus Types 1 and Types 2

The challenge viruses were propagated and assayed in cells that were pregrown as monolayer cultures in plastic tissue culture flasks and 96-well plates, using cell culture media appropriate for the host cell cultures. The following viruses and host cell cultures were employed:

	<u>Challenge Virus</u>	<u>Host Cell Type</u>
45	Herpes simplex type 1 (HSV-1) strain E-377	Continuous-passage African green monkey kidney (Vero)
50	Herpes simplex type 2 (HSV-2) strain MS	Continuous-passage African green monkey kidney (Vero)

On the day of use, a weighed sample of each compound to be evaluated was dissolved and diluted in serial 10^{0.5} dilutions in the culture medium appropriate for each virus-host cell system.

55 CPE-Inhibition Assay Procedure

Mammalian cells were pregrown as monolayers in wells of COSTAR 96-well tissue culture plates using suitable cell culture media. Stock viruses were pretitered according to the method of Reed and Muench

(Amer. J. Hyg. 27:493-497, 1938) and diluted in cell culture medium to yield 32 CCID₅₀ (cell culture infectious dose, 50%) units per 0.1 ml. Antiviral assays were designed to test seven concentrations of each compound, from cytotoxic to noncytotoxic levels, in triplicate against each of the challenge viruses in microtiter plate wells containing suitable cell monolayers. To each of the replicate cell cultures were added 5 0.1 ml of the test drug solution and 0.1 ml of virus suspension. Cell controls containing medium alone, virus controls containing medium and virus, and drug cytotoxicity controls containing medium and each drug concentration were run simultaneously with the test samples assayed in each experiment. The covered plates were incubated at 37°C in a humidified atmosphere containing 5% CO₂ until maximum CPE (cytopathogenic effect) was observed in the untreated virus control cultures. The cell monolayers were 10 examined microscopically for virus-induced CPE and for drug cytotoxicity.

Antiviral activity was determined by calculating the degree of inhibition of virus-induced CPE in drug-treated, virus-infected cell cultures by means of a virus rating (VR). The VR is a standard weighted measurement of antiviral activity taking into account both the degree of CPE inhibition and drug cytotoxicity, and is determined by a modification of the method of Ehrlich et al. (Ann. N.Y. Acad. Sci. 130: 5-16, 1965) as 15 described below. CPE was graded for each individual culture in each microtiter plate well according to the following scale:

- 4 = 100% of the cells affected by virus;
- 3 = 75% of the cells affected by virus;
- 2 = 50% of the cells affected by virus;
- 20 1 = 25% of the cells affected by virus;
- 0 = No CPE; normal cell monolayer.

The VR was calculated as 0.1 of the sum of the numerical differences between the recorded CPE grade of each test well and that of the corresponding virus control in the culture plate. Numerical differences between the scores of test wells containing a drug concentration which was partially cytotoxic (p) and their 25 corresponding virus controls were halved.

The minimum inhibitory drug concentration which reduced the cytopathogenic effect (CPE) by 50% (MIC₅₀) was calculated by using a regression analysis program for semilog curve fitting. A therapeutic index (TI) for each active compound for each susceptible virus was determined by dividing the minimum cytotoxic concentration of the test compound by the MIC₅₀. Test results are provided in Table 1.

30 B. Evaluation of Compounds for Activity Against Human Cytomegalovirus (HCMV) - Virus Yield Reduction Assay

Human diploid embryonic lung (MRC5) cells were grown in 35 mm wells of 6-well tissue culture plates. 35 Subconfluent cell monolayers were rinsed with phosphate-buffered saline (PBS) and were exposed to 0.5 ml/well of HCMV (strain AD169) suspension for 1.5 hours at 37°C. The virus suspension was diluted in MEM + 2% fetal bovine serum (FBS) to yield a multiplicity of infection (MOI) of approximately 0.1 plaque forming units (PFU)/cell.

Following the virus adsorption period, the inocula were removed and infected cell layers were rinsed with 40 PBS. Aliquots (2.0 ml) of each test drug concentration (dissolved in MEM supplemented with 2% FBS) were dispensed into triplicate cell cultures: two virus-infected cultures and one uninfected cytotoxicity control culture (exposed to medium without virus for 1.5 hours). Untreated virus-infected control cultures and untreated, uninfected cell control cultures were fed with medium alone. The culture plates were incubated at 37°C in a humidified atmosphere of 2% CO₂ in air.

45 All cell culture fluids were replaced with fresh drug and medium 48 hours postinfection (p.i.).

On Day 6 p.i., the cell layers were examined microscopically for cytopathogenic effect (CPE) and drug cytotoxicity. The test and virus control cultures were then harvested by subjecting the cell layers to one cycle of freeze-thawing. The cellular material was scraped into the ambient medium and the contents from replicate cultures were pooled, dispensed into cryotubes and stored at -135°C.

50 Drug cytotoxicity was determined quantitatively by a method based on the reduction of the tetrazolium salt, 3-(4,5-dimethyl-thiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) by mitochondrial enzymes of viable host cells to MTT formazan (T. Mosmann, 1983). Drug cytotoxicity controls and cell controls were treated with MTT (dissolved in culture medium) followed by 20% SDS (in 0.02 N HCl) to dissolve the crystals of MTT formazan. The blue color of the MTT formazan was measured spectrophotometrically at 570 nm. Drug cytotoxicity was determined by comparing the absorbance (O.D.) of each drug cytotoxicity control with the mean O.D. of the cell control cultures and expressed as percent of control.

The harvested test and virus control samples were thawed and the infectious virus yield was determined by plaque assay in MRC5 cells grown in 12-well cluster plates. Inhibition of HCMV replication by

each test compound was determined by comparing the progeny virus yields in the drug-treated cultures with the progeny virus yield in the untreated, virus-infected control cultures. Test results are provided in Table 2.

5 C. Evaluation of Compounds for Activity Against Varicella-Zoster Virus (VZV) - Plaque Reduction Assay

The compounds of the invention were evaluated for selective activity against varicella zoster virus (VZV) utilizing a plaque reduction assay procedure. The challenge virus was a clinical isolate designated DM625, obtained from Dr. Richard Whitley of the University of Alabama Hospitals, Birmingham, Alabama. The virus had been passaged and titrated in cultures of human foreskin fibroblasts (HFF).

10 For the plaque reduction assay, sixth to twelfth passage human foreskin fibroblasts were seeded in wells of 12-well tissue culture plates and incubated at 37°C in a humidified atmosphere containing 2% CO₂ in air.

15 Subconfluent HFF were rinsed with MEM and exposed to 0.5 ml/well of a suspension of VZV diluted in MEM + 2% FBS for 2 hours at 37°C. Following the virus adsorption period, the inocula were removed and the infected cell layers were rinsed with MEM. Triplicate VZV-infected cell culture wells were treated with 1.0 ml of each concentration of test compound (in MEM + 2% FBS). Six untreated virus-infected cell cultures and triplicate untreated uninfected cell cultures were fed with 1.0 ml of MEM + 2% FBS to serve as controls. Wells containing uninfected HFF were treated with each concentration of test compound to monitor the test compound cytotoxicity. The 12-well plates were incubated at 37°C in the CO₂ incubator. At 48 hours post-virus infection (p.i.), fluids in all plate wells were replaced with fresh test compound and/or culture medium.

20 25 Six days p.i., the VZV plaques were counted (unstained, low magnification). The effect of each concentration of test compound on plaque formation was determined by comparing the mean number of plaques in the replicate test compound-treated cultures with the mean plaque counts of the untreated virus control cultures.

25 30 The test compound cytotoxicity control cultures were examined microscopically for gross morphologic changes, then treated with MTT and 30% SDS. The blue color of the MTT formazan was measured spectrophotometrically at 570 nm. Test compound cytotoxicity was determined by comparing the absorbance (O.D.) of each test compound control with the mean O.D. of the cell control cultures and expressed as percent of control.

35 Test results are provided in Table 3. The MIC₅₀ value is the minimum concentration of test compound required to inhibit plaque formation by 50%.

35 D. Alternate Method For Evaluation Of Compounds For Activity Against Herpes Simplex Virus Type 1

Neutral Red Dye Uptake Assay For Determining In Vitro Antiviral Activity

40 Vero cell monolayers were harvested by trypsinization. The number of viable cells per ml. was determined by staining an aliquot with trypan blue and counting in a hemocytometer. Cell densities were adjusted in growth medium to contain 4×10^5 cells/ml. 96-well sterile tissue culture plates were seeded with 100 µl/well of the adjusted cell suspensions, i.e., 4×10^4 cells/well. Seeded plates were incubated overnight at 37°C with CO₂.

45 After overnight incubation, monolayers were approximately confluent. The growth medium was removed and the monolayers in each cell were infected with 100 µl of virus diluted in maintenance medium to produce approximately 90% cytopathogenic effect (CPE) after 2 to 3 days incubation. The virus was allowed to adsorb for 1 hour at 37°C with 4 to 6% CO₂. Controls for cell growth were overlayed with virus-free maintenance medium. The maintenance medium containing residual virus was removed.

50 The test compounds were dissolved and/or diluted in maintenance medium to the concentration desired for testing and were added to the wells of the plate. Aliquots (100 µl) of each concentration were added to wells in replicate (duplicate or triplicate). Controls for virus activity were overlayed with drug-free maintenance medium.

Replicate wells containing only maintenance medium served as controls for background absorbance levels.

55 The plates were incubated at 37°C with CO₂ until approximately 90% CPE was observed in the virus infected control cells (usually 2 to 3 days). After incubation, the medium was removed from all the wells. 100 µl of neutral red solution was added to each well and the plate was incubated at 37°C without CO₂ for 2 hours. After the 2 hour incubation, the excess neutral red solution was removed. The plates were washed with 100 µl/well of PBS, pH 7.2 and then the PBS was removed.

The neutral red stain taken up by the viable cells was extracted by adding 100 μ l/well of acidified methanol, pH 1.0. (The acidified methanol fixed the cells to the well). The plate was allowed to stand at room temperature for at least 15 minutes to allow for maximum extraction. The amount of neutral red stain extracted into the methanol was quantified by determining the absorbance at a wavelength of 540 nm.

5

Reagents

1% aqueous Neutral Red Salt was prepared by mixing 1 gram of neutral red salt in 100 ml of distilled water.

- 10 Neutral Red Staining Solution was prepared by mixing 100 ml of 1X PBS, pH 7.2, 1 drop of 0.5% aqueous phenol red, 2-3 drops of 2N HCl (until solution turns yellow-orange) and 0.66 ml of 1% aqueous neutral red.

Acidified methanol was prepared by mixing 8 drops of 2N HCl in 100 ml of methanol.

- 15 10X Phosphate Buffered Saline (PBS), pH 7.2, was prepared by mixing 12.36 grams of Na₂HPO₄ (anhydrous), 1.80 grams of NaH₂PO₄ (monohydrate) in distilled water, adjusting the pH to 7.2 and bringing the final volume to 1 liter.

Results

- 20 The percent CPE in virus controls was determined by the following formula:

$$\frac{\text{Abs}_{540} \text{ cell controls} - \text{Abs}_{540} \text{ virus controls}}{\text{Abs}_{540} \text{ cell controls}} \times 100 \text{ Abs}_{540} \text{ cell controls}$$

The percent CPE in cells infected with virus and treated with the test compound was determined by the following formula:

$$\frac{\text{Abs}_{540} \text{ cell controls} - \text{Abs}_{540} \text{ test compound}}{\text{Abs}_{540} \text{ cell controls}} \times 100 \text{ Abs}_{540} \text{ cell controls}$$

- 25 A plot was made of the percent CPE versus concentration of the test compound. The concentration of test compound at which 50% CPE would be observed is read from the dose-response curve and is the MIC₅₀ (μ g/ml). The concentration of test compound which is toxic to 50% of control cells is shown as the TD₅₀. Test results are provided in Table 4.

- 30 E. Alternate Method For Evaluation of Compounds For Activity Against Herpes Simplex Virus Types I and II

CPE Inhibititon Assay Procedure (MTT)

- 35 Vero cells were pregrown as monolayers in wells of COSTAR 96-well tissue culture plates using suitable cell culture media. Stock viruses were pretitered according to the method of Reed and Muench (Amer. J. Hyg. 27 493 (1938)) and diluted in cell culture medium to yield 32 CCID₅₀ (cell culture infectious dose, 50%) units per 0.1 mL. Antiviral assays were designed to test six concentrations of each compound, from cytotoxic to noncytotoxic levels, in triplicate against each of the challenge viruses in microtiter plate wells containing cell monolayers. To each of the replicate cell cultures were added 0.1 mL of the test-compound solution and 0.1 mL of virus suspension. Two compounds were evaluated per plate. The following controls were included:

- (1) Cell controls containing cells + medium;
- (2) Untreated, virus-infected cell controls;
- (3) Test-compound cytotoxicity controls containing uninfected, test-compound treated cells;
- (4) Test-compound color controls - test-compound + medium (no cells); and
- (5) Reagent (experiment medium) controls - medium only (no cells).

- 45 The covered plates were incubated at 37°C in a humidified atmosphere containing 2% CO₂. When cytopathogenic effect (CPE) in untreated virus control wells reached 100%, 20 μ l of 3-(4,5-dimethyl-thiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) (dissolved in PBS at 5 mg/mL) was pipetted into each of the plate wells. The plates were incubated at 37°C for six hours; then 40 μ L of 30% SDS (in 0.02 N HCl) was added to each well. After overnight incubation at 37°C, the blue color of the MTT formazan was measured spectrophotometrically at 570 nm. The optical density (OD) value of each culture is a function of the amount of formazan produced which is proportional to the number of viable cells. A computer program was utilized to calculate the percent (CPE) reciprocal of % CPE reduction of the virus-infected wells and % cell viability of the uninjected test-compound control wells.

55 Test results are provided in Table 5. The IC₅₀ value is the minimum test-compound concentration (μ g/mL) that inhibited CPE by 50%, calculated by using a regression analysis program for semilog curve fitting. The TC₂₅ value is the minimum test-compound concentration (μ g/mL) that reduced cell viability by

25%.

The term parenteral as used herein includes subcutaneous injections, intravenous, intramuscular, intrasternal injection, or infusion techniques.

Injectable preparations, for example, sterile injectable aqueous or oleagenous suspensions may be formulated according to the known art using suitable dispersing or wetting agents and suspending agents. The sterile injectable preparation may also be a sterile injectable solution or suspension in a nontoxic parenterally acceptable diluent or solvent, for example, as a solution in 1,3-butanediol. Among the acceptable vehicles and solvents that may be employed are water, Ringer's solution, and isotonic sodium chloride solution. In addition, sterile, fixed oils are conventionally employed as a solvent or suspending medium. For this purpose any bland fixed oil may be employed including synthetic mono- or diglycerides. In addition, fatty acids such as oleic acid find use in the preparation of injectables.

Suppositories for rectal administration of the drug can be prepared by mixing the drug with a suitable nonirritating excipient such as cocoa butter and polyethylene glycols which are solid at ordinary temperatures but liquid at the rectal temperature and will therefore melt in the rectum and release the drug.

Solid dosage forms for oral administration may include capsules, tablets, pills, powders, and granules. In such solid dosage forms, the active compound may be admixed with at least one inert diluent such as sucrose lactose or starch. Such dosage forms may also comprise, as is normal practice, additional substances other than inert diluents, e.g., lubricating agents such as magnesium stearate. In the case of capsules, tablets, and pills, the dosage forms may also comprise buffering agents. Tablets and pills can additionally be prepared with enteric coatings.

Liquid dosage forms for oral administration may include pharmaceutically acceptable emulsions, solutions, suspensions, syrups, and elixirs containing inert diluents commonly used in the art, such as water. Such compositions may also comprise adjuvants, such as wetting agents, emulsifying and suspending agents, and sweetening, flavoring, and perfuming agents.

The foregoing is merely illustrative of the invention and is not intended to limit the invention to the disclosed compounds. Variations and changes which are obvious to one skilled in the art are intended to be within the scope and nature of the invention which are defined in the appended claims.
